

# Grid Features Validation Packet -- 8Z3ESD

Every trace in this packet is simulated output from a fitted, multi-conductance single-compartment model of this cell, integrated deterministically -- not a raw current-clamp recording. What is being evaluated here is the feature-extraction methodology applied on top of that model: spike detection, burst/tonic classification, post-inhibitory rebound detection, sag depth, and spike-frequency adaptation. Each figure below reruns the actual classification algorithm on a real simulated trace and marks what it found directly on the trace.

Silencing threshold: -16.75 nA | 2500 points sampled across the current grid

Burstiness index: 0.224

Firing-rate/current slope: not available (no tonic points to fit)

## Contents:

### 1. Feature overview

Every extracted-feature panel across the full current grid -- what the rest of this packet verifies.

### 2. Representative traces

Every distinct response pattern this cell produces, then one full-detail trace per pattern.

### 3. Spike detection

Every spike the automated detector found, marked on real traces.

### 4. Spike-detection threshold sensitivity

How stable spike counts are across detection thresholds.

### 5. Independent cross-check of spike detection

A second detection method compared against the primary one.

### 6. Tonic / bursting / silent classification

Interspike intervals and the statistical test for two separate interval populations.

### 7. Bimodality test

The full statistical-separation evidence behind the tonic/bursting distinction.

### 8. Burst-onset-then-silence detection

A leading onset burst followed by cessation, vs. one that sustains.

### 9. Post-inhibitory rebound detection

Rebound spikes after release from hyperpolarization, and the latency cutoff used.

### 10. Sag depth

The baseline voltage, search window, and trough behind the sag measurement.

### 11. Spike-frequency adaptation

Early vs. late interspike intervals on a real, sustained tonic trace.

### 12. Firing rate vs. injected current

Firing rate vs. current, with the linear fit used to summarize it.

### 13. Reproducibility check

How often re-simulation reproduces the original classification.

# 1. Feature overview: 8Z3ESD's full current grid

## TEST PHASE

## RECOVERY PHASE

Every panel below is computed from the same 2500-point grid of held and injected current levels: which pattern each point fires in and whether it rebounds after release from hyperpolarization (top row), firing rate and burst structure (second row), rebound spike count, latency, and peak voltage (third row), and sag depth, adaptation, and burst size (bottom row). Two single-number summaries condense the whole grid: a burstiness index of 0.224 (the fraction of points classified bursting) and a firing-rate-vs-current slope that is not available (no tonic points to fit). The rest of this packet does not add new results -- it re-derives individual pieces of this same grid from real simulated traces so each one can be checked by eye against the panel it feeds.

## 2. Representative traces

bursting, then a burst-like rebound  
held=-16.07 nA, injected=-15.94 nA

bursting, then no rebound  
held=-15.72 nA, injected=-15.58 nA

bursting, then a sustained (tonic) rebound  
held=-13.67 nA, injected=-13.40 nA

silent (no firing), then a burst-like rebound  
held=-15.04 nA, injected=-17.39 nA

silent (no firing), then no rebound  
held=-16.41 nA, injected=-16.30 nA

tonic firing, then a burst-like rebound  
held=-15.04 nA, injected=-13.04 nA

tonic firing, then a sustained (tonic) rebound  
held=-12.99 nA, injected=-2.90 nA

One representative trace for each distinct combination of response-to-current-step pattern and rebound pattern observed across this cell's full 2500-point grid of held and injected current levels: gray is the held baseline before the current step, red is the response during the current step, and blue is the recovery period after release back to the held level. Each combination is represented by its most clearly-expressed example among the grid points that produced it. Every panel shares the same voltage (-58 to 26 mV) and time (0-5500 ms) axes so amplitude and duration are directly comparable by eye -- without this, a small subthreshold wobble and a full-amplitude spike train would each be independently rescaled to fill the same panel and look equally prominent.

# 8Z3ESD: bursting during the current step, then a burst-like rebound

# 8Z3ESD: bursting during the current step, then no rebound

# 8Z3ESD: bursting during the current step, then a sustained (tonic) rebound

8Z3ESD: silent (no firing) during the current step, then a burst-like rebound

# 8Z3ESD: silent (no firing) during the current step, then no rebound

# 8Z3ESD: tonic firing during the current step, then a burst-like rebound

# 8Z3ESD: tonic firing during the current step, then a sustained (tonic) rebound

## 5. Independent cross-check of spike detection by upstroke shape

As an independent check, each candidate spike was also required to show a fast upstroke -- a rate of voltage rise of at least 10 mV/ms within 20 ms before the peak (the convention used by Bean, 2007) -- rather than amplitude alone. 444 of 444 candidate spike(s) were confirmed by this stricter test; the two methods agree on every spike in this window.

As an independent check on a random sample of 20 grid points from this cell, every spike detected by amplitude alone was additionally required to show a fast upstroke in voltage (rather than amplitude alone) before being counted, an independent detection criterion not used for classification elsewhere in this report. Agreement close to 100% shows that the simpler amplitude-based detector used throughout is not missing any spikes that a shape-based check would catch.

```
python src/generate_validation_packet.py --cells XB2IQX DFJ1K3 8Z3ESD MXIC4S  
source: cell_held_injected_grid.pkl -> resimulate_point() -> find_silencing_threshold.detect_spikes_dvdt_confirmed()
```

## 10. Sag depth

Sag depth is the difference between the voltage just before the current step (-38.0 mV) and the most hyperpolarized point reached afterward (-51.5 mV), giving 13.6 mV of sag -- a hallmark of the hyperpolarization-activated current ( $I_h$ ) partially repolarizing the cell during the step. The trough was found by searching stopping early at the first spike, 9 ms in.

# 11. Spike-frequency adaptation

The adaptation ratio -- the mean of the last 3 interspike intervals divided by the mean of the first 3 -- is 1.02. Firing stays roughly constant over this window.

## 12. Firing rate vs. injected current

8Z3ESD -- firing rate vs. injected current, no holding current

0 non-silent points with a clearly-classified firing pattern, sampled across injected current with no holding current applied (points still below firing threshold, which would otherwise bias the linear fit toward zero, are excluded). This firing-rate/current slope is one of the features used to characterize this cell in the cross-cell comparison; here it is plotted directly against the data it was fit to.

```
python src/generate_validation_packet.py --cell_held_injected_grid.pkl --cell_grid_features.pkl (extract_grid_features.compute_fi_slope())
source: cell_held_injected_grid.pkl -> cell_grid_features.pkl (extract_grid_features.compute_fi_slope())
```

### 13. Reproducibility check

40 random points from this cell's grid were re-simulated independently and compared against the classification stored from the original sweep. Match rate: 95%. Except at zero holding current, where the cell's own steady-state limit cycle is reused exactly, each holding-current level is reached by integrating forward from whichever already-settled level is numerically nearest -- this model is known to show path-dependent (hysteretic) settling near dynamical transitions, so a re-simulation that approaches a borderline point along a different path than the original sweep can occasionally land on a different classification right at that boundary.

`python src/generate_validation_packet.py --cells XB2IQX DFJ1K3 8Z3ESD MXIC4S`
